#### Advertising Data

#### Advertising consists of:

- ▶ the Sales of a product in 200 different markets
- the advertising budgets for three different media:
  - TV
  - Radio
  - Newspaper
- It is not possible to directly increase the sales of the product
- On the other hand, it is possible to control the advertising expenditure in each of the 3 media

#### Introduction

- Suppose we observe a quantitative response Y and p different predictors,  $X_1, X_2, \ldots, X_p$
- We assume there is some relationship between Y and  $[X_1, \ldots, X_p]$ . that can be written in a general form as

$$Y = f(X_1, X_2, \dots, X_p) + \epsilon$$

- lacktriangleright f represents the systematic information that the predictors provide about Y
- $ightharpoonup \epsilon$  represents an  $\emph{error}$  term that is a catch-all for what we miss with the model

#### Data set Advertising

#### Response:

▶ Y: Sales

#### Predictors:

► X<sub>1</sub>: TV

 $ightharpoonup X_2$ : Radio

▶ X<sub>3</sub>: Newspaper

#### Relationship:

Sales = 
$$f(TV, Radio, Newspaper) + \epsilon$$

#### Linear relationship

 $\triangleright$  One possible form for f() is a linear relationship:

$$Y = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p + \epsilon$$

- ▶ It assumes a linear dependence of *Y* on the predictors
- $\triangleright \beta_0, \beta_1, \dots, \beta_p$  are unknown constants also known as the model *coefficients* or *parameters*
- ▶ The linearity is in the parameters (i.e. coefficients)

#### Linear relationship

$$Y = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p + \epsilon$$

Sales = 
$$\beta_0 + \beta_1 \text{ TV} + \beta_2 \text{ Radio} + \beta_3 \text{ Newspaper} + \epsilon$$

#### Introduction

The challenge involves finding parameter estimates denoted by

$$\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p$$

that provide the "best" approximation for Y:

$$Y \approx \hat{\beta_0} + \hat{\beta_1} X_1 + \dots + \hat{\beta_p} X_p$$

or more commonly

$$\hat{Y} = \hat{\beta}_0 + \hat{\beta}_1 X_1 + \dots + \hat{\beta}_p X_p$$

#### Introduction

- Linearity is a BIG assumption.
- ► True regression functions are rarely linear.
- ► Although it may seem overly simplistic, linear regression is extremely useful both conceptually and practically.

# Simple Linear Regression

- ► Simple Linear Regression = Univariate regression
- ightharpoonup One predictor varibale X and one response variable Y
- lacktriangle One predictor varibale x and one response variable y

$$Y = \beta_0 + \beta_1 X + \varepsilon$$

We assume a linear model

$$Y = \beta_0 + \beta_1 X + \varepsilon$$

#### where:

- $\triangleright$   $\beta_0$  and  $\beta_1$  are two unknown constants also known as coefficients or parameters
- $\triangleright$   $\beta_0$  represents the *intercept*
- $\beta_1$  represents the *slope*
- $\triangleright$   $\varepsilon$  is a vector if error terms

In vector notation:

$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x} + \boldsymbol{\varepsilon}$$

#### where:

- y is the vector representing the response variable
- x is the vector representing the predictor variable
- $\triangleright$   $\varepsilon$  is the vector representing the error term

#### Some vector-matrix notation

In matrix notation:

$$\mathbf{y}_{n \times 1} = \mathbf{X}_{n \times 2} \times \boldsymbol{\beta}_{1} + \boldsymbol{\varepsilon}_{1}$$

which can be represented by:

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ 1 & x_3 \\ \vdots & \vdots \\ 1 & x_n \end{bmatrix} \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix} + \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \vdots \\ \varepsilon_n \end{bmatrix}$$

Note that if the data is center (mean = 0)

$$\mathbf{y} = \beta_1 \mathbf{x} + \boldsymbol{\varepsilon}$$

then there is no intercept term  $\beta_0$ 

#### Some vector-matrix notation

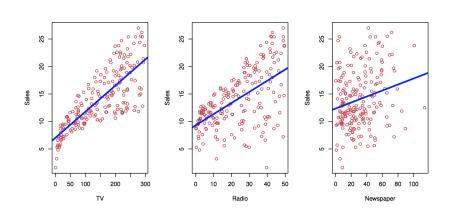

With centered data we have:

$$\mathbf{y}_{n\times 1} = \mathbf{x}_{n\times 1} \times \beta + \mathbf{\varepsilon}_{n\times 1}$$

which can be represented by:

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{bmatrix} \begin{bmatrix} \beta_1 \end{bmatrix} + \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \vdots \\ \varepsilon_n \end{bmatrix}$$

# Various simple regressions

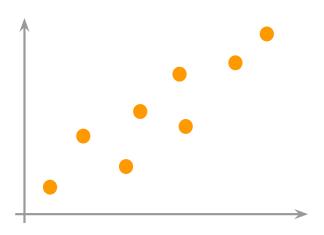

#### Assuming the model

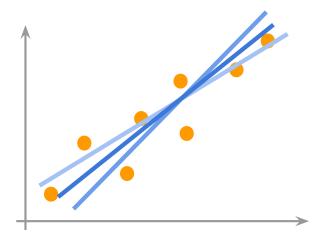

$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x} + \boldsymbol{\epsilon}$$

and given some estimates  $\hat{\beta_0}$  and  $\hat{\beta_1}$  for the model coefficients, we predict future sales using

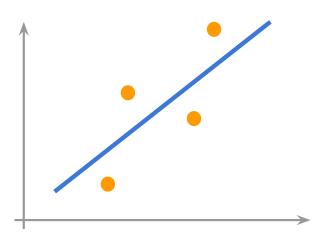

$$\mathbf{\hat{y}} = \hat{\beta_0} + \hat{\beta_1} \mathbf{x}$$

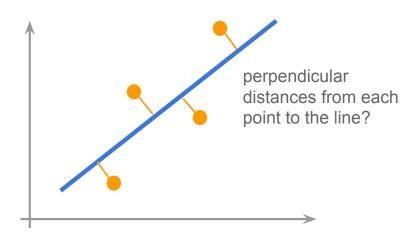

where  $\hat{\mathbf{y}}$  indicates a prediction of  $\mathbf{y}$ 

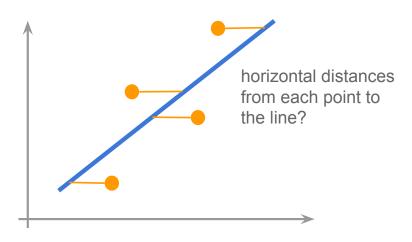

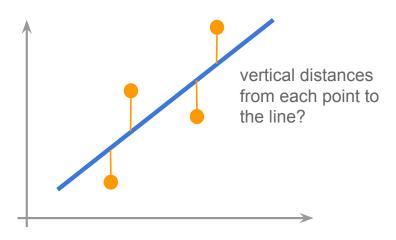

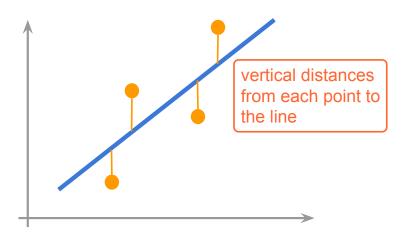

How to find the "best" fitting line?

# Estimation of Parameters

Let  $y_i = \hat{\beta}_0 + \hat{\beta}_1 x_i$  be the prediction for y based on the ith value of x

- Let  $y_i = \hat{\beta}_0 + \hat{\beta}_1 x_i$  be the prediction for y based on the ith value of  $\mathbf{x}$
- ▶ Then  $e_i = y_i \hat{y_i}$  represents the *i*th residual

- Let  $y_i = \hat{\beta}_0 + \hat{\beta}_1 x_i$  be the prediction for y based on the *i*th value of x
- ▶ Then  $e_i = y_i \hat{y_i}$  represents the *i*th residual
- ▶ We define the Residual Sum of Squares (RSS) as

$$RSS = e_1^2 + e_2^2 + \dots + e_n^2$$

▶ The **Least Squares** approach chooses  $\hat{\beta}_0$  and  $\hat{\beta}_1$  to minimize the RSS

The starting point is to write the model as:

$$\mathbf{e} = \mathbf{y} - (\beta_0 + \beta_1 \mathbf{x})$$

For convenience we define a quadratic loss function

$$L = \sum_{i=1}^{n} e_i^2 = \sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i)^2$$

To minimize L we we take partial derivatives with respect to each of the two parameters

Thus,

$$\frac{\partial L}{\partial \beta_0} = 2 \sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i)(-1) = 0$$

and

$$\frac{\partial L}{\partial \beta_1} = 2 \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)(-x_i) = 0$$

The solutions for  $\beta_0$  and  $\beta_1$  would be ontained by solving the so-called *normal equations* 

$$\sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i) = 0$$

and

$$\sum_{i=1}^{n} (x_i y_i - x_i \beta_0 - \beta_1 x_i^2) = 0$$

## Estimation of the parameters by OLS

#### The **Least Squares** coefficients are:

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2}$$

$$\hat{\beta_0} = \bar{y} - \hat{\beta_1}\bar{x}$$

where:

$$\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$$
 and  $\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$ 

# Estimation of the parameters by OLS

Notice that:

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2}$$

is equivalent to:

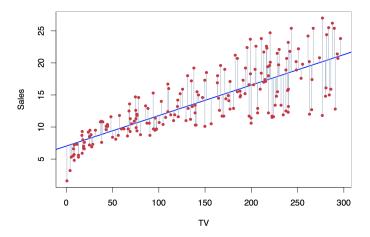

$$\hat{\beta}_1 = \frac{cov(\mathbf{x}, \mathbf{y})}{var(\mathbf{x})}$$

```
# number of observations
n <- nrow(Advertising)

# model matrix
x <- Advertising$TV

# reponse variable
y <- Advertising$Sales</pre>
```

```
# slope
b1 \leftarrow cov(x, y) / var(x)
b1
## [1] 0.04753664
# intercept
b0 \leftarrow mean(y) - b1 * mean(x)
b0
## [1] 7.032594
```

The least squares fit for the regression of Sales on TV. In this case a linear fit captures the essence of the relationship, although it is somewhat deficient in the left of the plot.

# Another perspective

# Projection

Notice that:

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2}$$

Can be expressed in vector notation as:

$$\hat{\beta_1} = \frac{\mathbf{y}^\mathsf{T} \mathbf{x}}{\mathbf{x}^\mathsf{T} \mathbf{x}}$$

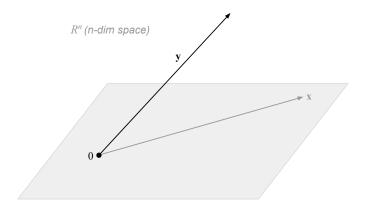

with  $\boldsymbol{x}$  and  $\boldsymbol{y}$  mean-centered.

#### Projection

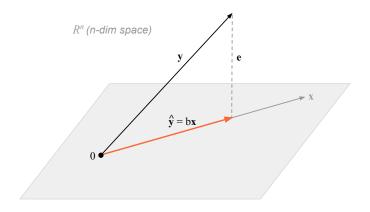

Thus, with centered variables  $\mathbf x$  and  $\mathbf y$ , the fitted values  $\hat{\mathbf y}$  are given by:

$$\begin{split} \hat{\mathbf{y}} &= \hat{\beta}_1 \mathbf{x} \\ &= \left(\frac{\mathbf{y}^\mathsf{T} \mathbf{x}}{\mathbf{x}^\mathsf{T} \mathbf{x}}\right) \mathbf{x} \\ &= \mathbf{x} \left(\frac{\mathbf{y}^\mathsf{T} \mathbf{x}}{\mathbf{x}^\mathsf{T} \mathbf{x}}\right) \\ &= \mathbf{x} (\mathbf{x}^\mathsf{T} \mathbf{x})^{-1} \mathbf{x}^\mathsf{T} \mathbf{y} \end{split}$$

# From variables perspective

# From variables perspective

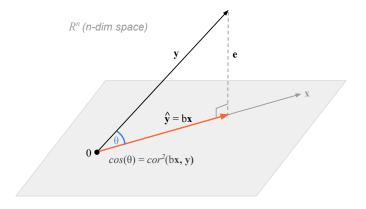

```
# number of observations
n <- nrow(Advertising)

# model matrix
x <- Advertising$TV - mean(Advertising$TV)

# reponse variable
y <- Advertising$Sales - mean(Advertising$Sales)</pre>
```

```
# slope
b1 \leftarrow sum(x * y) / sum(x * x)
b1
## [1] 0.04753664
# intercept
b0 <- mean(Advertising$Sales) - b1 * mean(Advertising$TV)
b<sub>0</sub>
## [1] 7.032594
```

# From variables perspective

#### Some Remarks

- There is nothing in the Least Squares method that requires statistical inference: formal tests of null hypotheses or confidence intervals.
- ▶ In its simplest form, regression analysis can be performed without statistical inference.
- ► The inferential part can sometimes be very useful but goes beyond the definition of a regression analysis.

#### Some Comments

- ► Linear Regression is a "simple" approach to supervised learning.
- ▶ Don't get fooled by the word "simple".
- "simple" ≠ easy / boring / uninteresting.
- ▶ I will use the terms *Regression Analysis* and *Regression Model* interchangeably.
